Lake Holden, July 7, 2010

DEP conducted chemical and biological sampling at Lake Holden in Orange County on July 7, 2010 in response to a home owner request concerning potential adverse effects from past and present use of alum to improve water clarity in the lake by reducing sediment nutrient availability. Overall, the water quality met the State of Florida’s water quality standards, but plant community data indicated that the lake did not meet biological expectations for a healthy, well-balanced lake.

Background

Although healthy, well balanced lake communities may be maintained even with some level of human disturbance, human activities may result in lake degradation. Human stressors include increased inputs of nutrients, sediments and/or pesticides from watershed runoff, undesirable removal of native shoreline and/or upland buffer vegetation, and introduction of nuisance (generally exotic) plants and animals. DEP has methods to evaluate if human activities have resulted in the condition where a particular waterbody has exceeded water quality criteria (Chapter 62-302, Florida Administrative Code), including whether adverse impacts to biological communities have occurred. DEP water quality standards are designed to protect designated uses of the waters of the state (e.g., recreation, aquatic life support), and exceedances of these standards are associated with interference with the designated use. Chlorophyll a is a measure of algal biomass in the water column. In clear, low alkalinity lakes (lakes where color is < 40 PCU and alkalinity is < 20 mg/L CaCO3), a healthy system is expected to have ≤ 6 µg/L of chlorophyll a. In colored (> 40 PCU) lakes or clear, high alkalinity (>20 mg/L CaCO3) lakes, healthy systems are expected to have ≤ 20 µg/L of chlorophyll a. Chlorophyll a values greater than those shown above may result in unwanted shading of aquatic plants and/or greater potential for harmful algal blooms. The Lake Vegetation Index (LVI) assesses how closely the plant community of a lake resembles a native undisturbed community. These tools are often used in conjunction with one another because it is possible to detect imbalance in the plant community while the algal community appears healthy (and vice versa).

Site Information

Lake Holden is an urban lake located within the Kissimmee River Basin in Orange County and the City of Orlando. Its surface area is approximately 265 acres (figure 1). Lake Holden was placed on the 303(d) List for nutrients and un-ionized ammonia. In 2006, the lake was included on the Adopted Verified List of Impaired Waters for nutrients and Trophic State Index (TSI). The Total Maximum Daily Load (TMDL) for Lake Holden is scheduled to be completed by September of 2011 to meet the State’s Consent Decree deadline. Between April 2005 and March 2006, three alum applications were conducted as part of a sediment inactivation project to lessen the availability of phosphorus in the sediment to the water column. The alum treatment was repeated beginning in January, 2010. On July 7, 2010, Lake Holden had the appearance of a clear, healthy lake considering its urban watershed.

Methods

Lake Holden was sampled on July 7, 2010 by the DEP Central District Office. Surface water samples were collected for analysis of nutrients, chlorophyll a, color, alkalinity and metals following DEP Standard Operating Procedures (SOP; see http://www.dep.state.fl.us/water/sas/ga/sops.htm) and met DEP quality assurance/quality control standards (see http://www.dep.state.fl.us/water/sas/ga/index.htm). For the LVI, species lists were developed for four of twelve sections of the lake (Figure 2), and the following information was derived from those lists: percent native species, percent invasive exotic species, percent sensitive species, and the coefficient of conservatism (C of C; a measure of how tolerant a species is to disturbance) of the dominant species. According to DEP SOP LT 7000, the LVI score ranges and categories are: (78-100) Exceptional; (38-77) Healthy; and (0-37) Impaired. DEP plans to propose a revised impairment threshold, in which scores of 46 and higher fully meet the expectation of a healthy, well balanced community, and scores below 46 are considered impaired. The LVI was sampled per DEP SOP FS7310 and calculated per DEP SOP LT7000.
Results

Water Quality

The July 7, 2010 water quality samples complied with water quality standards (Table 1). Since 2001, nutrients and chlorophyll concentrations have decreased. In 2001, total phosphorus values were as high as 0.05mg/L, total nitrogen reached 1.77mg/L, and chlorophyll a reached 45.78µg/L in 2003. Secchi depth, which was as low as 1.5 ft in 2002, was 8 ft during this sampling event.

Lake Vegetation Index

The LVI score for Lake Holden was 30 out of a possible 100 points, corresponding with an “impaired” designation. Table 2 contains the species list and occurrence information for this sampling event. Although there were substantial stands of native, submersed, beneficial vegetation such as Vallisneria and Najas guadalupensis, the common occurrence of invasive exotic plants (nine in total) reduced the LVI score. The Lake Holden vegetation community would be improved by reducing the abundance of these invasive exotic plants. See Table 2.

Summary

Lake Holden is in a period of transition. The historic nutrient load from Lake Holden’s watershed resulted in prominent algal growth and elevated chlorophyll a. (45.78µg/L on October 2, 2003) Elevated chlorophyll may cause unfavorable conditions for aesthetics, recreation and healthy biological function. The ongoing management plan to reduce the nutrient flow from Lake Holden’s watershed and inactivate historical nutrients in the lake’s sediments appears to be very effective, since current nutrient and chlorophyll concentrations were quite low. While these management activities are also attempting to reduce invasive plant species and promote native plant species, the LVI score indicates that additional exotic plant removal is still warranted. The Florida Department of Environmental Protection will continue to monitor Lake Holden, in conjunction with local agencies, through the TMDL process to gauge the success of future lake management, and to ensure the lake meets water quality and biological standards outlined in Chapter 62-302, Florida Administrative Code.

Thank you for your interest in maintaining the water quality of Florida’s lakes. Please feel free to contact us if you have any questions.

Phytoplankton

The algal community in the water column of Lake Holden was dominated by various species of green algae. Based on July 7, 2010 phytoplankton results, dominant algae groups were green (60%), blue-green (29%), and diatoms (5%). Dominance in algal groups varies naturally throughout the year, but prolonged dominance of blue-green algae, or cyanobacteria, may be associated with a higher risk for harmful algal blooms.
Table 2. Species list for the July 7, 2010 LVI at Lake Holden
An asterisk (*) indicates an invasive exotic plant species. P = present, D = dominant, C = codominant.

**Figure 1.** Bathymetric map of Lake Holden. Florida LAKEWATCH personnel created this map using differentially corrected global positioning equipment (GPS). Data were collected June 22, 2006. Scale and map contours are in feet and were generated using kriging technique in Surfer® software package (Golden CO). The center of the lake is located at Latitude 28°30’3” and Longitude 81°23’43”. On this date, the lake surface area was calculated at 257 acres (104 hectares) and the lake level was estimated at 91.54 feet. MSL using a Trimble Unit Pro XRS GPS. This is only an approximate bathymetric map and should not be used for navigation.

**Figure 2.** Sampling map of Lake Holden. Sections 1, 4, 7, and 10 were sampled for the Lake Vegetation Index. The water quality sample was collected from the lake center.
